Five Percent Report

Federal Highway Administration Highway Safety Improvement Program

Illinois Department of Transportation

August 2008

CH2MHILL

Executive Summary

As part of the Highway Safety Improvement Program (HSIP), states are required to submit an annual report to the Federal Highway Administration (FHWA) describing at least five percent of highway locations exhibiting the most pressing safety needs. This *Five Percent Report* will help Illinois gain an understanding of the nature and extent of safety problems, to provide guidance on where safety investments are needed, and to provide a basis for tracking the progress toward improving safety in the state. Significant progress has been made in providing a more rigorous analysis technique for the report, and the expansion of the dataset to include more sites and site specific information than the previous year.

Various changes affect the selection of FIVE PERCENT locations between 2007 and 2008. Additional information provided in the 2008 report is the inclusion of state unmarked routes, and the inclusion of intersections of state routes with local jurisdiction highways. This expanded crash data were not considered in the 2007 or previous reports. Another significant difference is the change in methodology from weighted crashes per mile to safety performance functions. Both changes are significant, as additional data are now being considered and analyzed in the most current proposed methodology. Between 2007 and 2008, there were 143 miles of overlap and 14 common intersections.

High priority locations have been identified in Illinois on the state and U.S. highway system, including freeways, urban and rural 2-lane and multilane facilities, and intersections. High priority counties were identified for local crashes, along with high-risk behaviors like speeding, alcohol involved collisions, and severe crashes where drivers were unrestrained. These analyses help to identify the most cost effective countermeasures by addressing needs in a multi-prong approach as laid out in the Illinois Comprehensive Highway Safety Plan (ICHSP). The Illinois Department of Transportation (IDOT) districts and local agencies use the *Five Percent Report* in conjunction with fatal and A-injury crash analysis as a basis for HSIP project submittals and operational safety improvements.

Overview of Basic Data

Data necessary to complete a study of this nature include locations of crashes, details of crash characteristics, roadway geometry information, and traffic volume data. The 2008 report uses statewide crash data for 2002 to 2006, and both 2005 and 2006 site-specific crash data for the local roadway system. Roadway feature data (2005) and average daily traffic (ADT) were furnished by the Illinois Roadway Inventory System (IRIS).

During the 5-year period 2002 to 2006, there were 112,689 fatal, A- or B-type injury crashes on Illinois roadways. Of those, 57 percent occurred on roadway segments and 43 percent were considered intersection related. For 2-lane rural roadways, a higher proportion of crashes are fixed object and overturn crashes, and there are a greater number of angle, turning and rear-end crashes for multilane urban roadways. Unsignalized intersections have a higher proportion of fixed object, overturn, and angle and turning crashes.

Selection of the FIVE PERCENT Sample

In conjunction with IDOT, the University of Illinois at Urbana-Champaign (UIUC) helped to prepare Safety Performance Functions (SPF) for state routes and intersections throughout Illinois. The UIUC categorized roadway segments and intersections by peer groups having homogenous characteristics so that an expected crash experience could be determined. Roadway segment peer groups reflect urban versus rural settings, as well as road classification and number of lanes. Intersection peer groups are based on area type and traffic control.

The Empirical Bayesian (EB) method was used to develop SPF equations for each peer group. Based on the expected crash experience a Potential for Safety Improvement (PSI) was calculated for each location. The PSI is the difference between the actual crash experience and the predicted crash experience for a given traffic volume within a specific peer group.

Per FHWA direction, analyses focused on the most severe crashes – specifically, fatal and A-type injury crashes. Therefore the PSI calculation was weighted to add emphasis to the most severe crashes. The weighted PSI calculations by location and peer group were ranked in ascending order. The largest PSIs per peer group were selected until five percent of the mileage by segment peer group or five percent of the intersections by peer group were accumulated. This process yielded just under 1,000 segments and more than 3,400 intersection locations. Since the number of intersection locations was so large, an additional screening was completed yielding 344 intersections in the five percent sample.

The available local road database consisted of 2005 and 2006 crash data with about 80 percent of the total number of crashes located. There is also limited average daily traffic and geometric information on the local road system. Because of these data limitations, it was not possible to calculate safety performance function for the local road system. Therefore crash location maps and aggregate crash characteristics by county were prepared.

The distribution of 'high risk' behaviors on a county by county basis was used to determine geographic bias or tendencies, and provide focus for application of resources to address these behaviors. Safety behavioral features considered in the high risk analyses were unrestrained drivers, impaired drivers, young or old drivers, and helmetless motorcycle riders.

Characteristics of the FIVE PERCENT Locations

Five percent of the total mileage of U.S. and State Routes was selected by peer group resulting in 858 segments and 774 miles. Most of the analyzed and selected locations were in urban areas, but most of the mileage was in rural areas. Sixty-nine percent of the total selected mileage falls into two peer groups: urban and rural 2-lane roadways.

While one would expect that five percent of the mileage would have five percent of the total number of fatal, A-, and B- type injury crashes, the selected FIVE PERCENT segments identified over 22 percent of the fatal, A- and B-type injury crashes on US and state routes in Illinois. Urban one-way arterials were even more noteworthy since the FIVE PERCENT locations identified over fifty percent of the fatal, A- and B-type injury crashes for US and state routes within this peer group.

FIVE PERCENT urban 2-lane and multilane roadways tend to have more angle and turning crashes than other roadways in this peer group. FIVE PERCENT rural freeways have more fixed object and overturn crashes, and FIVE PERCENT urban freeways have more rear-end and same direction side swipe crashes than the unselected locations in their respective peer groups.

The FIVE PERCENT intersections account for 0.6 percent of the intersections analyzed and represent over 7 percent of the fatal, A- and B-type injury crashes that have occurred at analyzed intersections over the analysis period. A majority of the fatal crashes occurred at minor leg stop controlled intersections. Overall, the FIVE PERCENT selected intersections have a higher percentage of angle and turning crashes.

Cook and Peoria counties have the highest overall rate of fatal, A-, B-, and C- type injury crashes on the local roadway system. Both of these counties were identified in the 2007 *Five Percent Report*, but the overall mean crash rate has been reduced from 0.77 to 0.72 million vehicle miles traveled (MVMT). Jo Daviess, Putnam, Jersey, Randolph, and Franklin counties continue to have high fatal and A-type injury crash rates.

Most of the local crashes happened in urban areas. As expected, single vehicle run-off-road was the primary crash type, accounting for roughly 59 percent of the crashes on rural local roads.

“High Risk” Behavior

Counties that exhibited the highest percentage of unrestrained drivers or occupants involved in a fatal or severe injury crash were located predominantly in the southern part of the state, while those that exhibited the highest percentage of impaired drivers involved in fatal or severe injury crashes were located in different districts throughout the state. Consideration should be given for a targeted educational and enforcement program aimed at both increasing seat belt use and reducing the practice of driving while impaired in each of these counties.

There is no discernable locational pattern of counties that exhibited the highest incidence of involvement in fatal or A-type injury crashes by drivers 18 years old or younger or by drivers 65 years old and older. All these counties may be considered as candidates for a targeted educational program directed toward safer driving practices by young or older drivers, or both.

Five counties, all located in the Chicago metropolitan area, accounted for roughly 46 percent of all helmetless motorcycle driver fatal crashes during the 5-year analysis period.

Treating the FIVE PERCENT Locations

While applicable countermeasure treatments will vary widely across classes or volume ranges, the list of FIVE PERCENT sites can form a strong basis for identifying candidate safety projects for the full range of highways and highway types. Further study is required, however, to ensure that data are current and to understand site conditions, such as pavement and shoulder condition, roadside characteristics, and right-of-way. Effective countermeasures

address the specific crash types that predominate at a site or can be expected given the type of roadway and level of traffic volume expected.

Site-specific analysis of implementation costs and expected long-term improvements should be conducted. Decisions should be made regarding prioritization and implementation of improvements as part of each District's or Agency's safety program. Where reconstruction or resurfacing/3R improvements are expected or programmed, select safety improvements can and should be incorporated. Districts may wish to defer treatment of a high-risk site in the immediate future if it is programmed for construction in a few years. Coordination with local units of government, especially law enforcement, is recommended to obtain maximum value for invested dollar.

Corridors where there are numerous closely spaced high-risk segments should be considered for potential improvements. Rather than spot treatment with selected countermeasures, it may be appropriate to consider low cost safety improvements (rumble strips, median guard rail) or reconstruction (alignment revisions, cross section improvements, etc.) over the length of the corridors.

Counties where there is evidence of significant overrepresentation of high-risk behavior (alcohol, lack of seat belt usage, speeding) may be subjects for multi-agency efforts to combat such behavior. Allocation of state funds to those counties may be the most cost-effective use of limited funds. Targeted enforcement activities, targeted public information efforts, or some combination of these may prove effective.

Conclusions

IDOT has directed additional resources toward the effort of improving the quality and timeliness of crash data. These initiatives have drastically improved IDOT's ability to identify problems, direct resources, create reports, further evaluate the effectiveness of projects and countermeasures in the future, and, ultimately, reduce fatalities and serious injuries on the public roadways of Illinois.

The FIVE PERCENT locations are one approach IDOT uses to identify and target safety dollars. In conjunction with implementation of the Comprehensive Highway Safety Plan (CHSP), IDOT has worked with multiple safety stakeholders at the state and local government level, along with private industry to develop programs and initiatives to reduce fatal and severe injury crashes.

IDOT is committed to an integrated "4E" approach to reducing fatalities and serious injuries on all Illinois roadways and will strive to continually improve.

1. Introduction

Signed on August 10, 2005, Section 1401 of the Safe, Accountable, Flexible, Efficient Transportation Equity Act: A Legacy for Users (SAFETEA-LU) amended Section 148 of Title 23 USC to create the Highway Safety Improvement Program (HSIP) as a core Federal Highway Administration (FHWA) program with separate funding. The purpose of HSIP is to reduce fatalities and serious injuries on public roads. As part of the HSIP, states are required to submit an annual report to the FHWA describing at least 5 percent of highway locations exhibiting the most pressing safety needs. According to FHWA, the *Five Percent Report* should address the following in each state:

- Locations where severe crashes, including specifically fatalities, are clearly overrepresented (referred to as *hazardous locations*)
- Potential remedies to the hazardous locations identified
- Estimated costs of the remedies to address the severe crashes
- Impediments to implementation of the remedies other than cost

The intent of the *Five Percent Report* is to gain an understanding of the nature and extent of safety problems, to provide guidance to the states as to where safety investments are needed, and to provide a basis for tracking the progress toward improving safety in each state. The FHWA is providing guidance for the process and content of the report. The FHWA Resource Center recommends that the report be as comprehensive as possible.

FHWA has required states to submit their draft reports no later than August 31, 2008, to enable FHWA to review, compile, and prepare its report to the U.S. Congress by October 1, 2008.

1.1 Study Approach

The State of Illinois had previously prepared this report for years 2006 and 2007. For the 2008 report, the Illinois Department of Transportation (IDOT) has modified its analysis procedure to account for the latest approaches in safety problem identification and evaluation. The analysis crash database and severity weighting have also changed from previous years. In 2008 fatal, A- and B-type injuries were used for analysis purposes. The severity weighting was 25 times for a fatal crash, 10 times for an A-type injury crash, and equivalent to a B-type injury crash. Safety Analyst is a tool FHWA is developing to identify and manage a systemwide program of site-specific improvements to cost effectively enhance safety. The tool uses the latest research and is scheduled to be available for use in July 2009. In advance of the product release, the state of Illinois has incorporated the analysis methodology of safety analyst for use in this report. This work will ease the transition to Safety Analyst and use the most current analysis procedures. This methodology requires the calculation of safety performance functions (SPF) to determine a site's potential for safety improvement (PSI).

High priority locations have been identified on the state and U.S. highway system, including freeways, urban and rural 2-lane and multilane facilities, and intersections. Additional information provided in the 2008 report is the inclusion of state unmarked routes, and the inclusion of intersections of state routes with local jurisdiction highways. This expanded crash data were not considered in the 2007 or previous reports.

High priority counties were identified for local crashes and high risk behaviors like speeding, alcohol involved collisions and severe crashes where drivers were unrestrained. These analyses help to identify the most cost effective countermeasures by addressing needs in a multi-prong approach as laid out in the Illinois Comprehensive Highway Safety Plan (ICHSP). This approach includes addressing site-specific needs with low cost safety improvements and systematic improvements along corridors or routes. Strategies also include increased and targeted enforcement and education programs to address concerns with younger drivers and drivers that are impaired, unrestrained, or speeding.

1.2 Report Application

The report has been submitted to the IDOT Districts, counties in Illinois, and the Illinois State Police to coordinate efforts to reduce the number of fatalities in the state of Illinois. Each IDOT district is expected to review the locations and provide responses to action that is recommended for each location. Coordination meetings are being held with the local agencies as well as the state police. The state and local police may make deployment decisions based on locations that have been identified as having high risk behaviors resulting in severe crashes. Multi-agency groups meet several times a year to address the transportation safety needs of the State and focus on the strategies by ICHSP emphasis area.

The IDOT districts and local agencies use the *Five Percent Report* in conjunction with fatal and A-injury maps and crash analysis as a basis for HSIP project submittals and operational safety improvements. Appendix B contains the district responses regarding the 2007 locations. This allows for straightforward tracking of the treatment of severe locations and is used to evaluate the success of the program to reduce fatalities on the transportation system.

2. Overview of Basic Data

Data necessary to complete a study of this nature include locations of crashes, details of crash characteristics, roadway geometry information, and traffic volume.

2.1 Crash Data

The State of Illinois is enhancing system coverage of crash data for safety analysis. For the 2006 report, crash data on the local system were not located in the state's geographic information systems (GIS) for site specific analysis purposes. By the 2007 report, the GIS system contained 1 year of crash data. For 2008, it contained 2 years of data. IDOT is on track to have at least 3 years worth of crash data in its GIS for the 2009 report.

Statewide crash data are used for the most recent available calendar years. The 2006 report used 1999 to 2003 crashes, the 2007 report 2001 to 2005, and the 2008 report 2002 to 2006. The 2007 crash data will be available during the summer of 2008. There is also an ongoing effort with several counties to locate local fatal and A-type injury crashes prior to 2005. Similar to 2006 and 2007, the crash records contain information on the date and time of the crash, severity, environmental conditions, roadway and vehicle type, crash type, and citations.

The database included crashes that involved fatality or A-, B-, or C-type injuries¹ and property damage only incidents. Per FHWA's direction to focus on the more serious crashes, the analysis used a subset of the total database in which C-type injury crashes and property damage only crashes were excluded. Fatal, A- and B-type injury crashes were retained to emphasize severe crashes and to enable sufficient numbers of crashes for deriving meaningful findings. Per IDOT's guidance, locations with a high preponderance of animal crashes were removed from the FIVE PERCENT selected locations. Note that animal crashes were included as part of the FIVE PERCENT analysis.

Only data readily available from IDOT's computer systems were used; no field data collection or verification was conducted to determine or analyze the 2008 locations. When the districts receive the FIVE PERCENT locations, they will field verify locations as necessary to provide project recommendations. The following specific data were used for this study:

- **State, U.S., and interstate routes**—2002 to 2006, geocoded crashes
- **Local roadways**—2005 to 2006 geo-coded crashes; 2002 to 2004 aggregate crashes not within GIS

¹ IDOT classifies crash severity as follows:

K Fatal—A traffic crash involving a motor vehicle in which at least one person dies within 30 days of the crash.

A Incapacitating injury—Any injury, other than fatal, that prevents the injured person from walking, driving, or normally continuing the activities he/she was capable of performing before the injury occurred. Inclusions: severe lacerations, broken/distorted limbs, skull injuries, chest injuries and abdominal injuries.

B Nonincapacitating injury—Any injury, other than a fatal or incapacitating injury, that is evident to observers at the scene of the crash. Inclusions: lumps on the head, abrasions, bruises, and minor lacerations.

C Reported, not evident—Any injury reported or claimed that is not listed above. Inclusions: momentary unconsciousness, claims of injuries not evident, limping, complaints of pain, nausea.

2.2 Roadway Inventory

Roadway feature data (2005) were furnished for all U.S., state, and most local roadways in Illinois. The data were compiled from the Illinois Roadway Inventory System (IRIS) system. The roadway data provided information on the characteristics of the roadway, the most important of which for this study are functional classification, length, and cross-sectional features (number of lanes, presence of median). Figure 2-1 summarizes centerline mileage of Illinois roadways by facility type. Table 2-1 indicates the specific mileage in each peer group that was analyzed. Detailed analysis was completed on 14 percent of the public roadways in Illinois. As noted, data are becoming more current, cleaner, and more comprehensive. It is expected that all public roadways will be analyzed using detailed site-specific methodology in future reports.

Traffic control information for 2005 was provided for all intersections along the state route system.

2.3 Traffic Counts

The Roadway Feature Inventory contained, for each marked roadway segment, average daily traffic (ADT) and the year it was counted. A marked roadway segment is a state and federally owned and maintained roadway with a state or federal name designation, such as IL 50, I-55, or U.S. 41. An unmarked roadway segment is state and federally owned and maintained roadway that does not have a state or federal route designation. Traffic counts were made predominantly between 2000 and 2006, but there were some earlier counts, mostly on low volume roads. The traffic counts in conjunction with the roadway cross-sectional feature were used to categorize segments for analysis.

Traffic volume was provided for only a small proportion of unmarked state routes and local roadways. The IDOT provided information to estimate traffic on roadways where it was not available. See Appendix A-3 for details.

2.4 Data Summary

There were more than 6,000 fatalities between 2002 and 2006, and 29 percent of the fatalities occurred at intersections (Figure 2-2). During the same 5-year period, there were 201,630 fatal, A-, and B-type injury crashes (Table 2-1). More than 108,000 of the crashes were analyzed in the FIVE PERCENT study. Table 2-1 summarizes the fatal and

^a Data shown in this column represents: total mileage for segments, and number of locations for intersections

^b Local crashes from 2001–2005 crash data

injury crashes on that have occurred on Illinois roadways by peer group. The U.S./state segments and U.S./state intersections with U.S./state routes or local routes were included in the FIVE PERCENT analysis. Some of the intersections analyzed were in an “undetermined” group because the traffic control type was unknown. Other local roads are those that were not included in the study at a detailed level. The other local road crashes represent both segment and intersection crashes.

Figure 2-3 indicates crash type by facility type for U.S. and state routes. For 2-lane rural roadways, a higher proportion of crashes are fixed object and overturn crashes, and there are a greater number of angle, turning and rear-end crashes for multilane urban roadways. Figure 2-4 represents crashes on U.S. and state route intersections by intersection type and shows that unsignalized intersections have a higher proportion of fixed object, overturn,

and angle and turning crashes While Illinois continues to make progress to fill data gaps, some factors such as the following may affect this analysis:

- Availability of local located crash data was limited to 2 years and not used in calculation of Safety Performance Functions for each peer group.
- Additional roadway feature inventory, to enable more robust analyses of potential countermeasures is not complete. Desired information for a complete database includes data for describing the roadside, traffic control, and horizontal and vertical alignment, and other roadway and construction characteristics.

3. Analysis Methodology

3.1 General Approach

In conjunction with IDOT, the University of Illinois at Urbana-Champaign (UIUC) helped to prepare Safety Performance Functions (SPF) for state routes and intersections throughout Illinois. This work was prepared in accordance with and in advance of the Safety Analyst tool being developed by FHWA to determine locations and cost-effective countermeasures for safety investments. See Appendix A-1 for the full report prepared by the UIUC.

The UIUC categorized roadway segments and intersections by peer groups for analysis. Peer groups represent homogenous characteristics so that an expected crash experience can be determined. There were 12 peer groups for the roadway segments and 8 for the intersections. Peer groups are segmented based on urban versus rural settings, and based on road classification and number of lanes. All U.S. and state marked and unmarked routes were coded with peer group identifiers. Specific segment peer group are shown in Table 3-1.

All intersections along U.S. and State routes, including intersections with other state routes or local roadways, were identified and give a peer group identifier based on area type and traffic control. IDOT provided a "Traffic-Control.shp" file that was used for determining intersection location and control criteria. IDOT also provided methodology for estimating average daily traffic (ADT) on local roadways where the ADT was missing from the Illinois Roadway Inventory System (IRIS). See Appendix A-3 for ADT estimating procedures used. In 2007 only the state to state route intersections (1,143 locations total) were evaluated due to limited data availability. The total number of intersections considered in 2008 was 54,880. Table 3-2 shows the number of intersections considered in 2008 by peer group.

TABLE 3-1
Roadway Segment Mileage Analyzed by Peer Group

Roadway Segment Peer Groups	Mileage Analyzed By Peer Group
1—Rural 2-Lane Highway	9,460
2—Rural Multilane Undivided Highway	34
3—Rural Multilane Divided Highway	316
4—Rural Freeway, 4 Lanes	1,337
5—Rural Freeway, 6+ Lanes	25
6—Urban 2-Lane Highway	2,350
7—Urban One-Way Arterial	193
8—Urban Multilane Undivided Highway	856
9—Urban Multilane Divided Highway	1,370
10—Urban Freeway, 4 Lanes	533
11—Urban Freeway, 6 Lanes	312
12—Urban Freeway 8+ Lanes	64
Total	16,850

The Empirical Bayesian (EB) method was used to develop SPF equations for each peer group. The equations model the crash experience based on geometry and traffic exposure between 2001 and 2005. The actual crash experience used for analysis was from 2002 to 2006. For the full equations see Appendix A-2.

Based on the expected crash experience a Potential for Safety Improvement (PSI) was determined for each location. The PSI is the difference between the actual crash experience and the predicted crash experience for a given traffic volume as shown in Figure 3-1.

TABLE 3-2
Number of Intersections Analyzed by Peer Group

Intersection Peer Groups	Number of Intersections Analyzed by Peer Group
1—Rural Minor Leg Stop Control	16,498
2—Rural All-Way Stop Control	369
3—Rural Signalized Intersection	202
4—Rural Undetermined Intersection	7,361
5—Urban Minor Leg Stop Control	17,737
6—Urban All-Way Stop Control	242
7—Urban Signalized Intersection	6,057
8—Urban Undetermined Intersection	6,414
Total	54,880

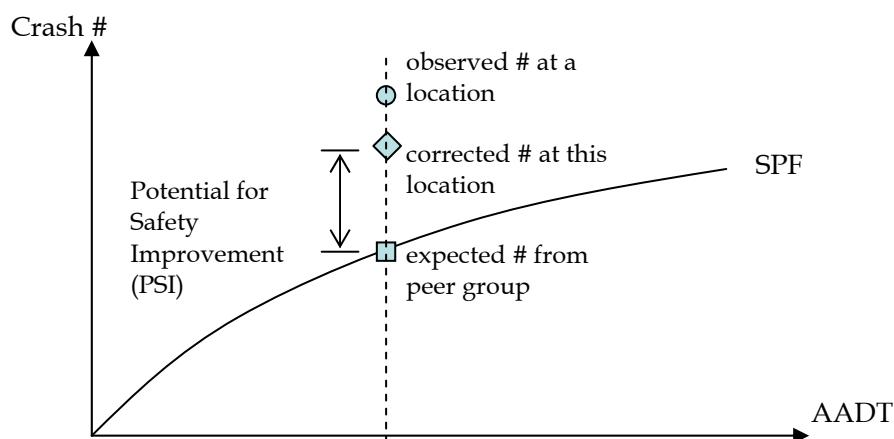

Figure 3-1: Determination of the Potential for Safety Improvement

Per FHWA direction, analysis should focus attention on the most severe crashes—specifically, fatal and A-type injury crashes. Therefore the PSI calculation was weighted to add emphasis to the most severe crashes. For analysis purposes several weighting methods were considered and evaluated. The recommended weighting scheme was 25 times a fatal crash, 10 times an A-type injury crash, and equivalent to a B-type injury crash. This was recommended because it placed an emphasis on fatal crashes without focusing too much on areas that have a few isolate crashes. See Appendix A-4 for more information on the study that was conducted to select the recommended weighting scheme.

PSI calculations were prepared for all roadway links as defined in IRIS, but the lengths of analysis segments varied dramatically. To minimize bias to smaller segments and evaluate the system more uniformly, analysis links were evaluated using a sliding window approach. Links were combined successively and overlapping to form segments at least 0.25 mile long in urban areas and at least 1 mile long in rural areas. This varied from previous years, where

segments were between 1 and 4 miles long and urban interstate had a one mile running average of in 0.1-mile increments.

The weighted PSI calculations by location and peer group were ranked in ascending order. The largest PSIs per peer group were selected until 5 percent of the mileage by segment peer group or 5 percent of the intersections by peer group were accumulated. In past years, 6 percent of mileage or locations were selected because it was known that some locations would be dismissed due to data issues, construction or reconstruction projects that took place late in the analysis period, more current information, or other issues. In 2008, the data set was larger, so it was reasonable to limit the selection to 5 percent so that it would be manageable. This process yielded just under 1,000 segments and more than 3,400 intersection locations. Since the number of intersection locations was so large, an additional screening was completed. The intersection PSI was plotted on a graph in descending order. As shown in Figure 3-2, intersections that had significantly higher PSIs or were above the knee of the curve were included in the study. Appendix A-5 contains the complete set of intersection selection graphics.

Note that the control type for intersection peer groups 4 and 8 are undetermined. Therefore, a FIVE PERCENT list was not developed for these locations. Instead, review of the locations was completed and intersections of interest were identified.

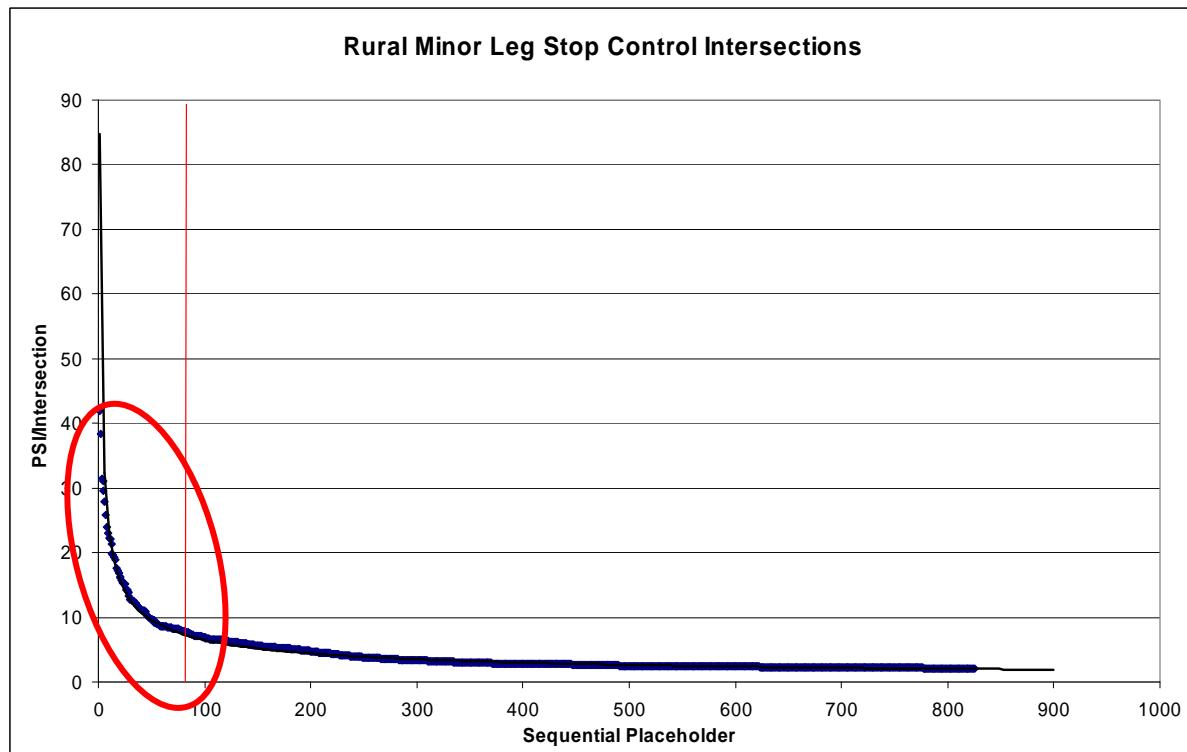

Figure 3-2: Intersection Location Selection Above the Knee of the Curve

3.2 Local Roadways

Located crashes in GIS on the local system do not include 100 percent of the crashes occurring from 2002 to 2006. Years 2005 and 2006 crash databases have about 80 percent of the total number of crashes located. There is also limited average daily traffic and geometric information on the local road system. Because of these data limitations it was not possible to calculate safety performance function for the local road system. Therefore crash location maps and aggregate crash characteristics by county were prepared.

3.2.1 Crash Location Maps

Location maps by district with major population centers detailed were prepared. To facilitate valid and useful visual comparisons between urban areas with high crash density common scales were used. These maps reflect 2005 and 2006 data only, as noted previously.

3.2.2 Crash Type Characteristics

Aggregate statistics were developed, to highlight or identify trends of 2005 and 2006 crash data. For instance, sets of two-by-two cross tabulations of crashes by type and severity, with other basic characteristics (light, pavement condition, etc.) on a statewide basis were developed, differentiating rural versus urban by using functional classification codes. These tables report both total frequency and percentages computed on both rows and columns. These tables are intended to be used as reference or benchmark statistics for analysis of trends at any county or any county project envisioned.

3.3 Countywide Analysis

The distribution of "high risk" behaviors on a county by county basis was used to determine geographic bias or tendencies, and provide focus for application of resources to address these behaviors.

Analyses were conducted by county of the following traffic safety behavioral features:

- Severe crashes in which the driver or occupant was unrestrained
- Severe crashes in which the driver was recorded as being impaired
- Severe crashes involving drivers 16 to 20 years old or younger
- Severe crashes involving drivers 65 years old or older
- Fatal motorcycle crashes in which the driver was helmetless

4. Five Percent Selection Results

This section highlights the FIVE PERCENT selected locations by peer group; U.S. and state route segments and intersections. The locations of the selected segments and intersections are shown in this section while maps and crash characteristics are shown in the appendix. Specifically the crash case identification numbers associated with selected locations are shown in Appendix C. Maps and crash characteristics of segments and intersections are shown in Appendix D and E respectively. For this report, exhibits have been reduced in size but can be made available at 24 × 36 for optimum viewing.

4.1 U.S. and State Route Roadway Segments

There are 3,243 unmarked routes, and 13,607 marked routes in Illinois, or 16,850 centerline miles total. Five percent of the total centerline mileage by peer group was selected resulting in 858 segments and about 774 miles. Table 4-1 indicates the number of segments and mileage analyzed and selected for each peer group. Most of the state of Illinois is rural and rural analysis segments were longer than urban segments due to the nature of the conditions. Therefore most of the mileage analyzed and selected was rural, 496 to 278 miles, however there were more urban locations analyzed and selected, 538 to 320 locations. Sixty-nine percent of the total selected mileage falls into two peer groups, the urban and rural 2-lane roadways. Likewise the analyzed and selected mileage for rural freeway with more than 6 lanes and urban freeways with greater than 8 lanes are very small. For example, only 1.7 miles were selected for the rural freeway with greater than 6 lanes.

TABLE 4-1
Number and Length of Segments Analyzed and Selected

Classification	Peer Group	Total Analyzed		5% Selected Locations	Segment Length
		Mileage	Segments	Mileage	
1	Rural 2-Lane	9,461	273	421.6	
2	Rural Multilane Undivided	34	1	2.2	Avg: 1.55 miles, Min: 0.82 miles, Max: 4.09 miles
3	Rural Multilane Divided	316	7	10.0	
4	Rural Freeway, 4 Lanes	1,337	38	60.4	
5	Rural Freeway, 6+ Lanes	25	1	1.7	
6	Urban 2-Lane	2,350	192	112.7	
7	Urban One-Way Arterial	193	27	9.7	
8	Urban Multilane Undivided	856	87	42.5	Avg: 0.52 miles, Min: 0.14 miles, Max: 2.99 miles
9	Urban Multilane Divided	1,370	140	66.3	
10	Urban Freeway, 4 Lanes	533	49	27.1	
11	Urban Freeway, 6 Lanes	312	36	15.6	
12	Urban Freeway, 8+ Lanes	64	7	3.8	
TOTAL		16,850	858	773.6	

Table 4-2 describes the number of fatal, A-, and B-type crashes that were analyzed and captured in the FIVE PERCENT locations by peer group. Overall five percent of the mileage was obtained and over 21 percent of the fatal, A- and B-type injury crashes were identified. For urban one-way arterials, over 50 percent of the fatal, A- and B-type injury crashes were identified in the FIVE PERCENT locations.

TABLE 4-2

Number of Crashes and Crashes per Mile for Segments Analyzed and Selected

Peer Group	Total Analyzed Segments		5% Selected Locations		% of Total
	K, A, B Crashes	Crashes Per Mile	K, A, B Crashes	Crashes Per Mile	
1—Rural 2-Lane	8,750	0.9	1,460	3.5	16.7%
2—Rural Multilane Undivided	61	1.8	12	5.5	19.7%
3—Rural Multilane Divided	632	2.0	48	4.8	7.6%
4—Rural Freeway 4 Lanes	3,464	2.6	268	4.4	7.7%
5—Rural Freeway 6+ Lanes	80	3.2	5	2.9	6.6%
6—Urban 2-Lane	7,705	3.3	2,051	18.2	26.6%
7—Urban One-Way Arterial	676	3.5	346	35.7	51.2%
8—Urban Multilane Undivided	5,420	6.3	1,765	41.5	32.6%
9—Urban Multilane Divided	9,650	7.0	3,002	45.3	31.1%
10—Urban Freeway 4 Lanes	3,606	6.8	528	19.5	14.6%
11—Urban Freeway 6 Lanes	6,415	20.6	790	50.6	12.3%
12—Urban Freeway 8+ Lanes	3,550	55.5	334	87.9	9.4%
TOTAL	50,009		10,609		21.2%

Table 4-3 describes the predominant crash type by peer group comparing the analyzed segments to the selected segments. In order to determine appropriate countermeasures for locations it is good to have an understanding of the predominant severe crash type. The table helps to understand overall and site specific analyses should be conducted. Two-lane and multilane roadways in the FIVE PERCENT selected locations tend to have more angle and turning crashes while rural freeways have more fixed object and overturn crashes and urban freeways have more rear end and same direction side swipe crashes.

Table 4-4 compares the statewide behavioral crash characteristics to those in the FIVE PERCENT segments. Behavioral crash characteristics include younger and older drivers, impaired drivers, restraint not used, and driving too fast for conditions. Comparing the percentage for statewide to the FIVE PERCENT locations helps to identify areas of focus for potential education or enforcement programs.

Tables 4-5 to 4-16 describe the locations of the selected segments. There is a corresponding map and table of crash characteristics in the appendix. The location is described in several different ways for ease of locating the segments. The inventory and begin and end stations are identified in both the Illinois Roadway Inventory System (IRIS) and the Division of Traffic Safety (DTS) system. Locations are also described by the route name, cross streets, district, and county. This table has been populated with information that was readily available in the IRIS database; therefore, there are some unidentified route or cross street names.

4.2 Intersections

All intersections along state routes were coded and evaluated, both state route and local intersections. There were 54,880 intersections analyzed as shown in Table 4-17. Table 4-17 also indicates the number of intersections selected as FIVE PERCENT locations by peer group. Note there is an undetermined category because the control type was unknown for this group of intersections. As a result analysis and PSI values will be misleading therefore these locations were reviewed but a FIVE PERCENT list was not prepared. A majority of the intersections selected in the FIVE PERCENT intersections were in urban areas. The selected intersections represent 0.6 percent of the total intersections analyzed and 7.1 percent of the fatal, A-, and B-type injury crashes as shown in Table 4-18. A majority of the fatal crashes occurred at minor leg stop controlled intersections. Overall, the FIVE PERCENT selected intersections have a higher percentage of angle and turning crashes, as shown in Table 4-19. Table 4-20 presents the behavioral crash characteristic comparison.

TABLE 4-17

Number of Intersections Analyzed and Selected

Classification	Peer Group	Total Number of Intersections Analyzed	Number of 5% Selected Locations	Percentage of Intersections
1	Rural Minor Leg Stop Control	16,498	80	0.5%
2	Rural All-Way Stop Control	369	11	3.0%
3	Rural Signalized	202	7	3.5%
4	Rural Undetermined	7,361	40	0.5%
5	Urban Minor Leg Stop Control	17,737	120	0.7%
6	Urban All-Way Stop Control	242	11	4.5%
7	Urban Signalized	6,057	40	0.7%
8	Urban Undetermined	6,414	35	0.5%
TOTAL		54,880	344	0.6%

Tables 4-21 to 4-26 describe the locations of the selected intersections and there are corresponding maps and tables of crash characteristics in the appendix. The location is described in several different ways for ease of locating the segments. The inventory and station are identified in both the Illinois Roadway Inventory System (IRIS) and the Division of Traffic Safety (DTS) system. Locations are also described by the route name, cross street, district, and county. This table has been populated with information that was readily available in the IRIS database therefore there are some unidentified route or cross street names. Appendix E contains maps of the locations as well as site specific crash characteristics and Appendix C contains the crash case identification numbers that can be used for looking up the specific crash reports.

4.3 Local Roadways

Figure 4-1 shows the countywide range of fatal and all injury crash rates per million vehicle miles traveled (MVMT), and Figure 4-2 shows the countywide range of fatal and A-type injury crash rates per MVMT for the 5-year analysis period.

Cook and Peoria counties have the highest overall rate of fatal plus injury crashes on the local roadway system. Both of these counties were identified in the 2007 *Five Percent Report*, but the overall mean crash rate has been reduced from 0.77 to 0.72. Jo Daviess, Putnam, Jersey, Randolph, and Franklin counties continue to have high fatal and A-type injury crash rates. The fatal and A-type injury crash rate in Jo Daviess county has increased and the fatal and A-type injury crash rate in Montgomery County has decreased.

Location maps and statewide aggregate statistics describe a general overview of safety on the local system. Because the location maps are 34 by 44 inches, they could not be included in this report; however, general observations based on the maps are presented below.

From the location maps and aggregate statistics, it is apparent that most of the local crashes (85 percent) happened in urban areas, with multivehicle collisions angle and turning (36 percent), and multivehicle other (29 percent) as the primary crash types occurring on the local roads. As expected, single vehicle run-off-road was the primary crash type, accounting for roughly 59 percent of the crashes, on the rural areas. About 74 percent of the nighttime (darkness) fatal crashes on rural areas were single-vehicle run-off-road.

Tables 4-27 through 4-40 summarize crash experience on local roads for the period from 2002 through 2006.

4.3.1 Unrestrained Drivers

Counties that exhibited the highest percentage of unrestrained drivers or occupants involved in a fatal or severe injury crash were located predominantly in the southern part of the state (Figure 4-3). The highest reported percentage was 53 percent in Fayette and Pope counties. Average percentage of unrestrained drivers involved in fatal or severe injury crashes was 31 percent.

Counties with high percentages of unrestrained fatalities are candidates for targeted public education and enforcement programs.

4.3.2 Impaired Drivers

Counties that exhibited the highest percentage of impaired drivers involved in fatal or severe injury crashes were located in different districts throughout the state (Figure 4-3). Over the 5 years for which data were analyzed, only 5 counties were found to have impaired driver involvement significantly higher than the statewide average of 37 percent. Counties with high percentages of impaired driving fatalities are candidates for targeted enforcement programs.

Consideration should be given for a targeted educational and enforcement program aimed at both increasing seat belt use and reducing the practice of driving while impaired in each of the 10 counties, which appeared on either lists of atypical high risk behavior.

4.3.3 Helmetless Motorcycle Fatalities

Five counties allocated in the Chicago metropolitan area accounted for roughly 46 percent of all helmetless motorcycle driver fatal crashes during the 5-year period from 2002–2006 (Figure 4-3). The number of fatal crashes per county (5 years) ranged from 101 (Cook) to 19 (Lake) compared with a statewide average of 4.54.

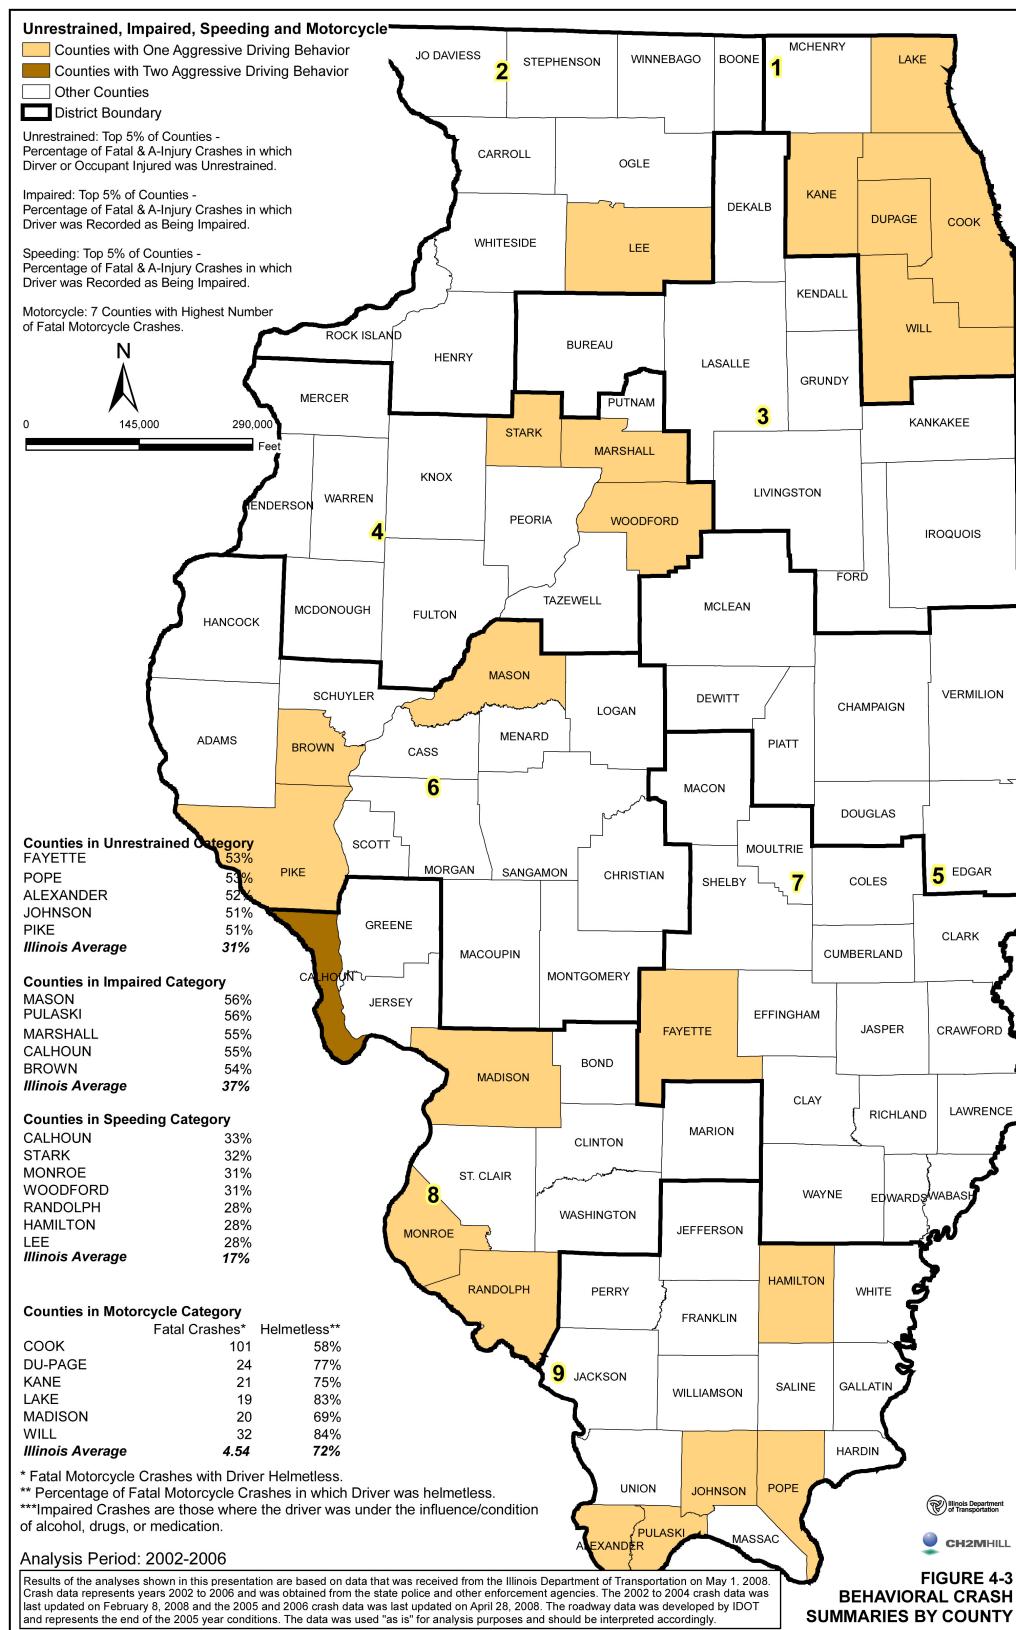

4.3.4 Young and Old Drivers

Counties that exhibited the highest incidence of involvement in fatal or severe injury crashes by drivers 18 years old or younger or by drivers 65 years old and older are shown in Figure 4-4. There is no discernible locational pattern. All the counties identified in the figure may be considered as candidates for a targeted educational program directed toward safer driving practices by young or older drivers, or both.

5. Comparison of 2007 and 2008 Locations

This section compares the results of the 2007 and 2008 analyses. There is a discussion of the differences in methodology and data, tables comparing overall analysis results and maps of specific location differences. Appendix F lists the matching locations.

Various changes affect the selection of FIVE PERCENT locations between 2007 and 2008. Most notably is the change in methodology from weighted crashes per mile to safety performance functions. Table 5-1 specifies the differences in analysis procedures between 2007 and 2008.

TABLE 5-1
Specific Differences between 2007 and 2008 Analyses

	2007	2008
Crash data	2001 to 2005, Animal crashes included. Selected locations that had a high percentage of animal crashes were removed.	2002–2006. Animal crashes were included Selected locations that had a high percentage of animal crashes were removed.
Roadway data ^a	2006 IRIS	2005 IRIS
Methodology	Weighted crashes per mile and weighted crashes per million entering vehicles	Safety performance functions and potential for safety improvement
Severity weighting	11 = Fatal and A-type injury crashes, 1 = B- and C-type injury crashes	25 = Fatal crashes, 10 = A-type injury crashes, 1 = B-type injury crash. C-type injury crashes were not included in the analysis
Routes Analyzed	U.S and State Marked routes, including Interstates and Interchanges	U.S and state marked and unmarked routes, including interstates
Routes Selected	Six percent of mileage based on analysis category (categories grouped by functional class and average daily traffic)	Five percent of mileage based on peer group (peer groups separated urban and rural and functional classification)
Route Segment Length	1 mile to 4 miles	Urban: minimum of 0.25 mile Rural: minimum of 1 mile
Intersections Analyzed	U.S. and state marked route intersections with other U.S. and state marked routes	U.S. and state marked and unmarked route intersections with other U.S. and state marked and unmarked routes and local roadways
Intersections Selected	6 percent of all analyzed intersections	Intersections with a PSI value above the knee of the curve

^a Safety performance functions were calculated in 2007 using 2005 roadway data. The functions were used in 2008 with the current crash data set of 2002 to 2006.

Tables 5-2 and 5-3 compare the number of locations analyzed in 2007 and 2008 as well as the common selected locations. There were 143 miles of overlap in common and 14 common intersections. Note that the undetermined intersections peer groups were not considered in this comparison.

Figure 5-1 and 5-2 shows the comparison to 2007 to 2008 segments and intersections respectively. The 2007 locations are shown in blue, the 2008 in green, and the overlapping parts in gold. The overlapping locations are distributed throughout the state without a discernable pattern.

TABLE 5-2
Comparison of Selected Segments from 2007 to 2008

	2007	2008
Mileage Analyzed	14,578	16,850
Mileage Selected	788	774
Mileage Unique	645	631
Mileage in Common *	143	143

Intersections Analyzed	1143	54,880
Intersections Selected	77	269
Unique Intersections	63	255
Intersections in Common	14	14

*Total number of intersections does not include interchanges that were analyzed in 2007.

6. Treating the Five Percent Locations

The FIVE PERCENT locations do not necessarily translate to actual prioritization of projects within limited budgets. They should be considered in a larger context, as mentioned previously. Applicable countermeasure treatments, their cost or ease of implementation, and resultant cost-effectiveness will vary widely across classes or volume ranges. Nevertheless, the list of sites can form a strong basis for identifying candidate safety projects for the full range of highways and highway types.

Data limitations discussed previously preclude definitive judgments or decisions regarding what should be done at each location. Further study is required to understand site conditions, such as pavement and shoulder condition, roadside characteristics, and right-of-way.

The IDOT intends to address each indicated location in the following manner:

- It is first necessary to confirm that each location has not been materially changed or improved since 2005, the roadway database used for analysis. Review of exhibits, tables, and underlying information by each agency is planned. Some locations may be removed from the map if it is determined they have been altered or reconstructed. For example, I-90/I-94 (Dan Ryan) was under construction during the analysis period and, therefore, may no longer have a safety issue.
- Analysis is limited to data contained in state crash, traffic, and geometric databases. Field review of sites is needed to confirm the accuracy of the data, to determine feasible engineering alternatives, and to provide the necessary information to enable evaluation of appropriate countermeasures for each site. Additional effort is needed to understand the specifics of crash types (time of day, pavement or weather condition, etc.).
- Updated crash information continually becomes available. This information will be used to confirm whether sites continue to pose safety risks and to adjust lists or maps as needed.
- The FIVE PERCENT locations were determined based on statewide analysis and therefore logical project termini must be determined. Maps with overlays of fatal and A-type injury crashes, high risk corridors, and other tools can be used to help identify logical termini to appropriately identify high risk area.
- Low cost safety improvements consistent with countermeasures discussed in the NCHRP Report 500 series and other recent research will be studied for each site. Effective countermeasures address the specific crash types that predominate at a site or can be expected given the type of roadway and level of traffic volume expected. Countermeasures have a cost both in dollar implementation terms and other factors of varying importance depending on the circumstances. The Illinois Countermeasure Tool may be implemented to assist with countermeasure selection on a systematic basis and the Benefit-Cost Tool may be invoked to assist with site specific countermeasure selection.

Road safety assessments (RSA) are being used throughout the state to identify high risk locations and develop countermeasures. RSAs may be a good method for addressing the FIVE PERCENT locations.

6.1 Countermeasures, Their Effectiveness, and Impediments to Their Implementation

Table 6-1 lists countermeasures and their attributes, based on the literature, and specifically the NCHRP Report 500 series, for consideration at the high-risk roadway segments and intersections, along with possible impediments to implementation of each countermeasure. A similar list can be created for interstates and interchanges.

Obtaining the maximum value for the effort and resources expended requires consideration of the cost-effectiveness of prioritizing a location and selecting the appropriate countermeasure. Prioritization does not necessarily mean that highest volume or highest frequency locations are addressed first. Cost or difficulty of implementation at one site may make it less of a priority than a lower volume site with fewer crashes for which a countermeasure can be readily implemented.

A simple “cost per crash eliminated” metric is recommended as a means of prioritizing and ultimately implementing countermeasures. This approach is similar to that taken in development of TRB Special Report 214, *Designing Safer Roads, Practices for Resurfacing, Restoration and Rehabilitation* (1987). In that document, researchers asserted that measures with a cost per crash eliminated of less than \$10,000 clearly are appropriate on safety reasons alone. When cost per crash eliminated is \$10,000 to \$50,000, cost-effectiveness may depend on other factors; when cost per crash eliminated exceeds \$50,000, it generally would not be cost-effective.

Cost per crash eliminated for the selected sites was prepared to determine the range of cost effectiveness. Values for expected countermeasure effectiveness were taken from NCHRP Report 500 series documents as well as information from Illinois Countermeasure Tool. Nominal implementation costs for lower cost improvements were assigned. FHWA’s *Lane Departure Strategic Action Plan* (March 2005) was referenced as well. The following general conclusions can help direct site-specific implementation:

- For lower volume roadways (fewer than 2,500 vpd), strategies that cost less than \$5,000 per mile generally are preferred to maximize total system effectiveness. Such strategies generally will include implementation of rumble strips, pavement edge drop treatments, enhanced delineation of objects or edges of pavement; placing of warning signs; and other treatments that do not require geometric changes, right-of-way and other complications.
- For moderate to higher volume 2-lane rural roadways, additional strategies such as removal of fixed objects, paving of shoulders, and improved or enhanced guardrail that have a higher cost (on the order of \$10,000 per mile) will be effective. Of course, should less costly treatments be as effective, they should be implemented first.
- High volume rural roadways and urban arterials experience crash types that would tend to require more extensive treatments. Rear-end crashes associated with driveway and other access requires widening for left-turn lanes, which in turn involves environmental, drainage, right-of-way and other complications. The number of crashes affected is greater, but so are both the cost and difficulty. A planning level threshold of \$50,000 to \$100,000 per mile may be cost-effective.

Site-specific analysis of implementation costs and expected long-term improvements should be conducted. Decisions should be made regarding prioritization and implementation of improvements as part of each District's or Agency's safety program. Where reconstruction or resurfacing/3R improvements are expected or programmed, selected safety improvements can and should be incorporated. Districts may wish to defer treatment of a high-risk site in the immediate future if it is programmed for construction in a few years. Coordination with local units of government, especially law enforcement, is recommended to obtain maximum value for invested dollar.

6.2 High Risk Corridors

High-risk corridors should be considered for potential improvements. High risk corridors are locations where there are numerous closely spaced high-risk segments. A more comprehensive study of the corridors should be conducted to determine the appropriate approach. Rather than spot treatment with selected countermeasures, it may be appropriate to consider reconstruction (alignment revisions, cross section improvements, etc.) over the length of the corridors. Types of safety problems and measures to address them may vary significantly. In many cases, it seems evident that the nature of the problem is related to access control, turning, and intersection-related conflicts, and in the cases of the arterials in Cook County, pedestrians.

6.3 High-Risk Behaviors

Counties where there is evidence of significant overrepresentation of high-risk behavior (alcohol, lack of seat belt usage, speeding) may be subjects for multi-agency efforts to combat such behavior. Allocation of state funds to those counties may be the most cost-effective use of limited funds. Targeted enforcement activities, targeted public information efforts, or some combination of these may prove effective.

6.4 Local Analyses

Counties where there is evidence of significant overrepresentation of crashes compared to tables provided (Tables 4-26 to 4-38) can focus efforts on particular types of crashes or locations. IDOT is in the process of locating most of the crashes that happened on the local system. It is recommended data starting from 2005 and ahead be used for future analysis. Meanwhile, the following recommendations can be used to identify high crash locations on the local road system, and these can be used by any county or any district:

- Share location data for 2005 and 2006 with County Engineer and Sheriff.
- From their local knowledge and other data, identify potential sites of interest to either monitor or consider treatment.
- For sites that might pose high risk, conduct simple counts to establish exposure base.
- Refer to threshold frequency and weighted frequency values for high crash locations from the statewide data analyses to help make these judgments.

The Illinois Countermeasure tool may be used to assist counties in allocating funds to reduce the greatest number of fatal and severe injury crashes.

TABLE 6-1
Potential Countermeasures and Impediments to Implementation for Roadway Segments

Typical Predominant Crash Types	Potential Countermeasure	Impediment to Implementation
2-Lane Rural Roadway		
Low to Moderate Traffic Volume		
Run off road, fixed object, and overturned	Install shoulder/edgeline rumble strips Improve or provide delineation Remove/relocate roadside obstacles Implement guardrail Pave shoulder; implement 'safety wedge' Flatten sideslope; reshape or regrade ditch Widen pavement/shoulder through curve Improve superelevation transition Advance curve warning (sign, rumble strips, etc.) Reconstruct horizontal curve	Requires paved shoulder in good condition Difficult snow removal Adverse effects on cyclists Undesirable noise levels Additional shoulder maintenance requirements Public reaction to tree cutting Coordination with environmental and public groups Potential widening and attendant impacts Additional maintenance requirements Requires sufficient width of unpaved shoulder Potential right-of-way required Affect drainage patterns (culvert and other issues) Potential environmental issues re: right-of-way Potential right-of-way required Right-of-way required; more extensive impacts Generally cost-effective for only higher volumes

TABLE 6-1
Potential Countermeasures and Impediments to Implementation for Roadway Segments

Typical Predominant Crash Types	Potential Countermeasure	Impediment to Implementation
Rear-end and same direction sideswipe	Relocate or remove driveways/minor intersections	Property owner objections to changes in access
	Widen to provide left-turn lanes	Potential right-of-way and environmental issues
	Enforce speed limit	Requires shoulder or other locations for enforcement
	Remove/relocate roadside sight obstructions	Diverts resources from other enforcement activities
	Improve vertical geometry to enhance sight distance	Public reaction to tree cutting Potential/probable right-of-way required
High Traffic Volume		
Rear-end and same direction sideswipe	Relocate or remove driveways/minor intersections	Property owner objections to changes in access
	Widen or place in median left-turn lanes	Potential right-of-way and environmental issues
	Enforce speed limit	Requires shoulder or other locations for enforcement
	Improve advance warning of signals, intersections	Diverts resources from other enforcement activities
	Install shoulder/edgeline rumble strips	Requires paved shoulder in good condition Difficult snow removal Adverse effects on cyclists Undesirable noise levels Additional shoulder maintenance requirements
Fixed object and overturned	Remove/relocate roadside obstacles	Public reaction to tree cutting Coordination with environmental and public groups
	Implement guardrail	Potential widening and attendant impacts Additional maintenance requirements
	Pave shoulder; implement 'safety wedge'	Requires sufficient width of unpaved shoulder

TABLE 6-1
Potential Countermeasures and Impediments to Implementation for Roadway Segments

Typical Predominant Crash Types	Potential Countermeasure	Impediment to Implementation
	Flatten sideslope; reshape or regrade ditch	Potential right-of-way required Affect drainage patterns (culvert and other issues) Potential environmental issues re: Right-of-way Adverse effects on cyclists Undesirable noise levels
Multilane Rural Roadway		
Rear-end and same direction sideswipe	Enforce speed limit Provide left-turn lanes	Diverts resources from other enforcement activities Potential right-of-way and environmental issues Affects median drainage
	Remove roadside sight obstructions	Public reaction to tree cutting Coordination with environmental and public groups
Fixed object and overturned	Install shoulder/edgeline rumble strips	Difficult snow removal Adverse effects on cyclists Undesirable noise levels Additional shoulder maintenance requirements
	Remove/relocate roadside obstacles	Public reaction to tree cutting Coordination with environmental and public groups
Urban Arterials		
Rear-end and same direction sideswipe	Add left turn lanes Implement median access control (raised)	Limited space may preclude or require right-of-way Proximity to major intersection may limit ability Objections of adjacent property owners (access) Affect drainage patterns

TABLE 6-1
Potential Countermeasures and Impediments to Implementation for Roadway Segments

Typical Predominant Crash Types	Potential Countermeasure	Impediment to Implementation
	Relocate/close driveways	Increase maintenance requirements
	Improve or establish progression for signals	Objections of adjacent property owners (access) Conflicts with signal requirements of crossing roads
	Restrict or prohibit left turns	Requires consensus of neighboring towns Increases out of direction travel Objections of adjacent property owners (access)
Pedestrian	Add/improve signalization along arterial for pedestrians	May degrade operational quality
	Implement raised median	Objections of adjacent property owners (access) Affect drainage patterns
	Revise and enforce speed limits	Increase maintenance requirements Requires shoulder or other locations for enforcement Diverts resources from other enforcement activities
Angle and turning	Add left turn lanes	Limited space may preclude or require right-of-way Proximity to major intersection may limit ability
	Implement median access control (raised)	Objections of adjacent property owners (access) Affect drainage patterns
	Relocate/close driveways	Increase maintenance requirements Objections of adjacent property owners (access)
	Restrict or prohibit left turns	Increases out of direction travel Objections of adjacent property owners (access)

7. Project Tracking and Program Evaluation

An important aspect of the FHWA Reporting requirement is tracking projects to ensure they are targeting a reduction of fatal crashes and program evaluation to provide evidence that the program is meeting the goals of reducing fatal and severe crashes. Each year the IDOT Bureau of Safety Engineering (BSE) helps to guide multi-agency stakeholders in addressing severe crashes in all ways possible. IDOT BSE works with the state police to encourage targeted enforcement programs and IDOT BSE works with other bureaus to ensure proper design standards for safety.

As seen in Appendix B, the IDOT districts use the *Five Percent Report* as one basis for program development. Table 7-1 shows the number of sites IDOT districts reviewed and the projects funded based on them. In 2007, IDOT reviewed 540 project locations; 84 projects were funded from HSIP or other funding sources.

TABLE 7-1
2007 Review of HSIP Projects

District	Number of 5 Percent Locations	Total Number of Reviewed Locations	2007 HSIP Project Approved, Submitted, or Soon will be Submitted			Future HSIP Submittals	Funded by Other Sources	Total 2007 Locations Funded or Anticipated Funding	
			Locations	%				Locations	%
1	170	170	17	10.0		0	0	17	10.0
2	46	46	3	6.5		7	0	10	21.7
3	44	44	3	6.8		6	5	14	31.8
4	38	38	1	2.6		1	1	3	7.9
5	20	20	1	5.0		0	1	2	10.0
6	26	26	5	19.2		0	10	15	57.7
7	30	30	1	3.3		0	5	6	20.0
8	85	70	0	0.0		0	1	1	1.4
9	52	47	6	12.8		1	9	16	34.0
Total	511	491	37	7.5		15	32	84	17.1

Some of the projects approved in 2006 are being implemented, but there are not enough after data to assess site-specific improvements. Overall fatal and severe crashes have been decreasing in Illinois.

In 2007 IDOT implemented a site evaluation form and IDOT is working on preparing site project tracking and program evaluation tools. The tools are still being tested but may be ready for the 2009 edition of the *Five Percent Report*.

8. Conclusions

Year 2008 is the third year of the FHWA FIVE PERCENT reporting requirement. Although most states continue to struggle with data availability, IDOT has made strides since last year and has been able to provide a more comprehensive *Five Percent Report* for 2008. The latest research is being used to identify high priority locations. This will help to transition to Safety Analyst when the tools become available.

IDOT directed additional resources toward the effort of improving the quality and timeliness of crash data, especially for the local roadway system. Initiatives that are ongoing at this time include expanding the use of electronic crash reports, assisting the local agencies financially to identify crash locations by geocode, and developing a Safety Data Mart system that will serve as a data warehouse for both internal and external users and allow various queries. These initiatives have drastically improved IDOT's ability to identify problems, direct resources, create reports, further evaluate the effectiveness of projects and countermeasures in the future, and, ultimately, reduce fatalities and serious injuries on the public roadways of Illinois.

The FIVE PERCENT locations are one approach IDOT uses to identify and target safety dollars. In conjunction with implementation of the Comprehensive Highway Safety Plan (CHSP), IDOT has worked with ISP and EMS to develop programs and initiatives to reduce fatal and severe injury crashes. For example, programs in place include safety performance functions, road safety assessments, photo enforcement in work zones and at intersections, systemwide application of cable guardrail, and program development of a rumble stripe policy. IDOT has developed a comprehensive "4E" approach that has been effective in reducing fatal and severe crashes (see Figures 8-1 and 8-2). IDOT is committed to the "4E" approach to reducing fatalities and serious injuries on all Illinois roadways and will strive continually to improve.

FIGURE 8-1
Number of Fatal Crashes in Illinois by Year
